ABSTRACT

For the first time, correlations among mixed-order moments of two or three flow harmonics $-(v_n^k, v_m^l, v_p^q)$ and (v_n^k, v_m^l, v_p^q) , with k, l , and q denoting the respective orders—are measured in xenon–xenon (XeXe) collisions and compared with lead–lead (PbPb) results, providing a novel probe of collective behavior in heavy ion collisions. These measurements compare a nearly spherical, doubly-magic ^{208}Pb nucleus to a triaxially deformed ^{129}Xe nucleus, emphasizing the sensitivity to initial-state geometry fluctuations arising from nuclear deformation. The dependence of these results ($v_n, n = 2, 3, 4$) on the shape and size of the nuclear overlap region is studied. Comparisons between v_2, v_3 , and v_4 demonstrate the importance of v_3 and v_4 in exploring the nonlinear hydrodynamic response of the quark-gluon plasma (QGP) to the initial spatial anisotropy. The results constrain initial-state model parameters that influence the evolution of the QGP. The CMS detector was used to collect XeXe and PbPb data at nucleon-nucleon center-of-mass energies of $\sqrt{s_{NN}} = 5.44$ and 5.36 TeV, respectively. Correlations are extracted using multiparticle mixed-harmonic cumulants (up to eight-particle cumulants) with charged particles in the pseudorapidity range $|\eta| < 2.4$ and transverse momentum range $0.5 < p_T < 3$ GeV/c.

1. Introduction

High energy heavy ion collisions at the LHC create a hot and dense state of strongly interacting matter, known as the quark–gluon plasma (QGP) [1,2]. The anisotropic shape of the overlap region between the two colliding nuclei generates pressure gradients that drive a collective anisotropic expansion of the medium. This collective behavior, known as anisotropic flow [3], is quantified through a Fourier decomposition of the single-particle azimuthal distribution of produced particles [4]:

$$\frac{dN}{d\phi} = \frac{1}{2\pi} \left[1 + 2 \sum_{n=1}^{\infty} v_n \cos n(\phi - \psi_n) \right], \quad (1)$$

where ϕ is the azimuthal angle of an outgoing particle, ψ_n denotes the n th-harmonic symmetry plane, and v_n is the n th flow harmonic. The coefficients v_2, v_3 , and v_4 correspond to elliptic, triangular, and quadrangular flow, respectively. These harmonics carry information about the initial spatial anisotropy and the subsequent medium response.

Event-by-event fluctuations in the positions of nucleons within the colliding nuclei lead to variations in the initial energy density, causing flow harmonics to fluctuate on an event-by-event basis. These fluctuations are studied through higher-order cumulants of the flow coefficients ($v_n^k, k > 1$). While second-order cumulants of a single flow harmonic and two-harmonic correlations are well explored [5,6], they are insensitive to non-Gaussian features of the flow probability distribution [7].

The study of mixed-order cumulants (correlations between different harmonics and orders, v_n^k and v_m^l , with $n \neq m$ and $k \neq l$) provides sensitivity to the nonlinear hydrodynamic response of the QGP. A purely linear response results in v_n scaling linearly with the corresponding initial-state eccentricity ϵ_n , which quantifies the transverse shape anisotropy of the collision zone immediately after impact [7].

In addition to event-by-event fluctuations in the energy density within each nucleus, the shape of the colliding nuclei, whether spherical or deformed, also influences the initial geometry of the overlap region and, consequently, the observed flow. The doubly magic lead (^{208}Pb) nuclei are nearly spherical [8], whereas xenon (^{129}Xe) nuclei are triaxially deformed [9]. This study therefore probes differences in the initial-state fluctuations arising from event-by-event variations in the nucleon configuration in collisions of nuclei with different shapes. The nuclear shapes are characterized by static ground-state deformation parameters constrained by low-energy nuclear physics measurements [10]. Following the parameterization used in low-energy nuclear structure studies, the nuclear density distribution is described using the Woods–Saxon formula:

$$\rho(r, \theta) = \frac{\rho_0}{1 + \exp[(r - R(\theta))/a_0]}, \quad (2)$$

where r is the radial distance from the center of the nucleus, θ is the polar angle relative to the symmetry axis, ρ_0 is the central density at $r = 0$, and a_0 is the nuclear skin depth. For a deformed nucleus, the

radial term $R(\theta)$ includes angular dependence via spherical harmonics:

$$R(\theta) = R_0 [1 + \beta_2 Y_{20}(\theta) + \beta_4 Y_{40}(\theta)], \quad (3)$$

where R_0 is the mean nuclear radius, β_2 and β_4 are the quadrupole and hexadecapole deformation parameters, respectively, and $Y_{\ell 0}(\theta)$ are the spherical harmonics.

This Letter presents a comprehensive study of multiparticle cumulants involving one, two, and three flow harmonics, including mixed higher-order correlations between different harmonics. The analysis is based on data collected with the CMS detector for XeXe and PbPb collisions at nucleon-nucleon center-of-mass energies of $\sqrt{s_{NN}} = 5.44$ and 5.36 TeV, respectively. The XeXe and PbPb data were recorded in 2017 and 2023, respectively, and correspond to integrated luminosities of $3.42 \mu\text{b}^{-1}$ [11–13] and 1.92 nb^{-1} . The key goals of this study are: (i) to investigate the effects of nuclear deformation on flow correlations using XeXe and PbPb comparisons, and (ii) to probe the nonlinear hydrodynamic response of the QGP using higher-order moments of v_n . The results are compared to a range of theoretical models to constrain the initial-state geometry and the transport properties of the QGP formed in heavy ion collisions at the LHC. Tabulated results for this analysis can be accessed in the HEPdata record [14].

2. The CMS detector

The CMS detector is centered around a superconducting solenoid with an internal diameter of 6 m, generating a 3.8 T magnetic field [15, 16]. Within the solenoid volume reside a silicon pixel and strip tracker, a lead tungstate crystal electromagnetic calorimeter (ECAL), and a brass-and-scintillator hadron calorimeter (HCAL), each composed of a barrel and two endcap sections. Forward calorimeters extend the pseudorapidity (η) coverage of the barrel and endcap detectors. Muons are identified using gas-ionization chambers embedded in the steel flux-return yoke outside the solenoid. The hadron forward (HF) calorimeters, positioned symmetrically 11.2 m from the interaction region, cover the range $3.0 < |\eta| < 5.2$ and also serve as luminosity monitors. These HF calorimeters use steel absorbers and quartz fibers as sensitive material, are azimuthally segmented into 20° modular wedges, and form towers of size 0.175×0.175 in $(\Delta\eta \times \Delta\phi)$. The silicon tracker, consisting of 1856 silicon pixel and 15 148 silicon strip detector modules, measures charged particles within $|\eta| < 2.4$. For nonisolated particles with transverse momentum $1 < p_T < 10$ GeV/c and $|\eta| < 1.4$, the typical track momentum resolution is 1.5%, and the transverse (longitudinal) impact parameter resolution ranges from 25–90 (45–150) μm . The CMS detector response is simulated in detail using Geant4 [17].

3. Event and track selections

Events from XeXe collisions are selected at the hardware level (level-1) by requiring the presence of both colliding bunches at the nominal interaction point [18]. A minimum energy deposit is required in at least one HF calorimeter tower, optimized to maximize event acceptance while suppressing noise from electromagnetic scattering and pileup (multiple interactions in a single bunch crossing). Pileup is negligible because the average number of collisions per bunch crossing is 0.018. At the high-level trigger [19], at least one reconstructed track in the pixel detector is required. Offline event selection further requires a minimum energy deposit of 3 GeV in each of at least three HF towers on both sides of the detector, to enhance selection of hadronic collisions and suppress ultraperipheral electromagnetic interactions. Events must contain a reconstructed primary vertex with at least two tracks, and located within 15 cm along the beam axis and 0.2 cm transversely relative to the nominal collision region. To reduce beam-gas interaction contamination, events with more than ten tracks must have at least 25% of tracks meeting high-purity quality criteria [15]. The overall event selection efficiency for hadronic events is approximately 95%. Track reconstruction follows algorithms similar to those used in proton-proton collisions [15].

For PbPb collisions, a cluster shape filter in the pixel detector ensures compatibility with particles originating from the primary vertex. The pileup rate is negligible (on average 0.0005 collisions per bunch crossing). Events are selected by requiring energy deposits of at least 4 GeV in two HF towers on both sides of the interaction point, favoring hadronic collisions. The same vertex location criteria as in XeXe data are used. Track reconstruction for the PbPb data utilizes a deep neural network algorithm trained with input variables including normalized χ^2 per degree of freedom, p_T resolution, and number of hits in the silicon pixel and strip detectors, based on conditions of the CMS detector from the reconstruction of earlier 2018 PbPb data [18].

In both the XeXe and PbPb systems, the analysis is restricted to primary charged particle tracks with $|\eta| < 2.4$ and $0.5 < p_T < 3.0$ GeV/c. For XeXe data, tracks are required to have impact parameter significances with respect to the primary vertex less than three standard deviations in both the beam direction (d_z) and the transverse plane (d_0), as well as a relative p_T uncertainty $\sigma_{p_T}/p_T < 10\%$. For PbPb data, the neural-network-based reconstruction imposes requirements on d_z and d_0 similar to those used for XeXe data [15, 20].

In this Letter, all observables are presented as functions of centrality, which is related to the degree of geometric overlap of the two colliding nuclei. The centrality percentage represents the fraction of the total inelastic hadronic cross section. A 0% centrality corresponds to a fully head-on collision, while higher centrality percentages indicate more peripheral collisions with smaller overlap. Experimentally, centrality is determined using the percentiles of the energy deposited in the HF calorimeters [21].

4. Analysis techniques

The two-particle correlation and multiparticle cumulant methods are discussed in Ref. [18]. In the two-particle correlation analyses, a charged particle from one p_T interval (the "trigger" particle) is paired with all of the remaining charged particles from the same p_T interval (the "associated" particles).

For a given trigger particle, the pairing is performed in two-dimensional (2D) bins of differences in η and azimuthal angle $(\Delta\eta, \Delta\phi)$. The signal and mixed-event distributions are defined as the per-trigger-particle yield of pairs in the same or mixed events:

$$S(\Delta\eta, \Delta\phi) = \frac{1}{N_{\text{trig}}} \frac{d^2 N^{\text{same}}}{d\Delta\eta d\Delta\phi}$$

$$M(\Delta\eta, \Delta\phi) = \frac{1}{N_{\text{trig}}} \frac{d^2 N^{\text{mixed}}}{d\Delta\eta d\Delta\phi}, \quad (4)$$

where N^{same} (N^{mixed}) is the number of same- (mixed-) event particle pairs in a given $(\Delta\eta, \Delta\phi)$ bin and N_{trig} is the number of trigger particles.

The mixed-event distribution is used to estimate the random combinatorial background and is constructed by pairing trigger particles in an event with associated particles from ten other randomly chosen events. Events are considered for mixing only if they belong to the same centrality bin (with a bin width of 5% or 10%) and the difference in their primary vertex locations along the beam axis is less than 2 cm.

The per-trigger-particle associated yield used to extract the v_n coefficients is found by normalizing the ratio of the signal and mixed-event distributions:

$$\frac{1}{N_{\text{trig}}} \frac{d^2 N^{\text{pair}}}{d\Delta\eta d\Delta\phi} = M(0, 0) \frac{S(\Delta\eta, \Delta\phi)}{M(\Delta\eta, \Delta\phi)}, \quad (5)$$

where $M(0, 0)$ is the mixed-event value at $(\Delta\eta, \Delta\phi) = (0, 0)$. This 2D normalized yield is then projected onto $\Delta\phi$ before fitting to a Fourier expansion. A selection of $|\Delta\eta| > 2$ is applied to suppress short-range nonflow correlations such as jets [22]. The fitting is done using:

$$\frac{1}{N_{\text{trig}}} \frac{dN^{\text{pair}}}{d\Delta\phi} = \frac{N_{\text{assoc}}}{2\pi} \left(1 + \sum_n 2V_{n\Delta} \cos(n\Delta\phi) \right), \quad (6)$$

where N_{assoc} is the number of associated particles in the selected kinematic interval, and $V_{n\Delta}$ denotes the n th Fourier coefficient.

Under the factorization assumption [23], $V_{n\Delta}(p_T^a, p_T^b) = v_n(p_T^a) v_n(p_T^b)$, and for trigger and associated particles from the same p_T range, the n th flow harmonic is extracted as:

$$v_n\{2, |\Delta\eta| > 2\} = \sqrt{V_{n\Delta}}, \quad (7)$$

where the first "2" in the v_n variable list refers to flow harmonics from two-particle correlations.

Multiparticle correlations involving four or more particles are studied with the Q-cumulant method [24], which incorporates track-by-track weights to correct for detector acceptance and efficiency [25]. This method allows the computation of cumulants that probe genuine multiparticle azimuthal correlations. Here, "genuine" correlations refer to irreducible multiparticle correlations that cannot be factorized into products of lower-order correlations, thereby providing sensitivity to collective behavior while suppressing nonflow contributions.

Within this framework, the four-particle v_n , $v_n\{4\}$, are extracted from four-particle cumulants. The two-particle cumulant $c_n\{2\}$ and four-particle cumulant $c_n\{4\}$ are defined as:

$$c_n\{2\} = \langle\langle e^{in(\phi_1 - \phi_2)} \rangle\rangle, \quad c_n\{4\} = \langle\langle e^{in(\phi_1 + \phi_2 - \phi_3 - \phi_4)} \rangle\rangle - 2c_n\{2\}^2, \quad (8)$$

where $\langle\langle \dots \rangle\rangle$ denotes an average performed in two steps: (i) first over all particles within a single event, and (ii) then over all events [24]. The corresponding four-particle cumulant is then obtained as

$$v_n\{4\} = \sqrt[4]{-c_n\{4\}}. \quad (9)$$

Four-particle symmetric cumulants (SC) measure correlations between the squared flow coefficients of two different harmonics, n and m :

$$\begin{aligned} SC(n, m) &= \langle\langle \cos(n\phi_1 + m\phi_2 - n\phi_3 - m\phi_4) \rangle\rangle \\ &\quad - \langle\langle \cos[n(\phi_1 - \phi_2)] \rangle\rangle \langle\langle \cos[m(\phi_1 - \phi_2)] \rangle\rangle \\ &= \langle v_n^2 v_m^2 \rangle - \langle v_n^2 \rangle \langle v_m^2 \rangle. \end{aligned} \quad (10)$$

This technique, originally introduced in Ref. [26], follows the same framework as described in Ref. [25]. The SC observable isolates correlations between fluctuations of flow harmonics beyond trivial statistical fluctuations. Similarly, symmetric cumulants of six particles $[SC(k, l, m)]$ involve combinations of the second orders of three different v_n coefficients [27].

Higher-order mixed harmonic cumulants (MHC) involving six or eight particles, also called m -observable cumulants [28] and first studied in Ref. [22], provide further suppression of nonflow correlations and probe the nonlinear hydrodynamic response and mode-coupling effects between different flow harmonics with enhanced sensitivity [22,28]. For example, the six-particle MHC involving v_2^4 and v_3^2 is defined as:

$$\text{MHC}(v_2^4, v_3^2) = \langle v_2^4 v_3^2 \rangle - 4\langle v_2^2 v_3^2 \rangle \langle v_2^2 \rangle - \langle v_2^4 \rangle \langle v_3^2 \rangle + 4\langle v_2^2 \rangle^2 \langle v_3^2 \rangle. \quad (11)$$

By construction, an m -particle cumulant removes contributions from correlations involving fewer than m particles, thereby reducing contamination from nonflow sources such as jets or resonance decays even further [28]. Similar cumulants can be defined for combinations of different orders of v_2 and v_3 , and also v_2 and v_4 , following the prescription in Ref. [22].

To enable more direct comparisons between different collision systems and between data and theoretical calculations, normalized cumulants are used. The normalized four- and six-particle symmetric cumulants (NSC) are defined as:

$$\text{NSC}(n, m) = \frac{SC(n, m)}{\langle v_n^2 \rangle \langle v_m^2 \rangle} \quad (12)$$

$$\text{NSC}(k, l, m) = \frac{SC(k, l, m)}{\langle v_k^2 \rangle \langle v_l^2 \rangle \langle v_m^2 \rangle}. \quad (13)$$

These normalizations improve the comparison between different collision systems and with theoretical predictions. They do so by removing

dependencies on the magnitudes of the flow coefficients, which can depend, for example, on the average p_T .

The normalized MHC (nMHC) scale the MHC by the average flow coefficients as:

$$\text{nMHC}(v_m^k, v_n^l) = \frac{\text{MHC}(v_m^k, v_n^l)}{\langle v_m^k \rangle \langle v_n^l \rangle} \quad (14)$$

$$\text{nMHC}(v_m^k, v_n^l, v_p^q) = \frac{\text{MHC}(v_m^k, v_n^l, v_p^q)}{\langle v_m^k \rangle \langle v_n^l \rangle \langle v_p^q \rangle}. \quad (15)$$

All cumulants are calculated using a $|\Delta\eta| > 2$ selection in both the numerator and denominator of the normalized cumulants, further reducing residual nonflow effects. The two-particle correlation method is retained for $v_n\{2, |\Delta\eta| > 2\}$ because it provides improved statistical precision while maintaining the same large pseudorapidity separation. In this regime, short-range correlations are strongly suppressed, and the resulting $v_n\{2, |\Delta\eta| > 2\}$ values are consistent with those obtained from the two-particle cumulant technique within the quoted systematic uncertainties. These small differences do not affect the conclusions found from the model-data comparisons.

The full mathematical details and further discussion of these methods can be found in Refs. [18,22,24].

5. Systematic uncertainties

Systematic uncertainties are evaluated from four main sources for both XeXe and PbPb collisions. Only the maximum relative uncertainties across all observables are quoted below, with the largest values found for measurements involving v_4 . In the following, percentage uncertainties are listed for XeXe collisions first, followed by the value for PbPb collisions. First, the track selection criteria are varied by comparing results using tighter (impact parameter significance < 2 standard deviations, relative p_T uncertainty $< 5\%$) and looser (5 standard deviations and 15%) selections, resulting in maximum uncertainties of 6 and 5%. Second, uncertainties from the primary vertex position are estimated by comparing results with vertex positions along the beam axis in the ranges $|z_{\text{vtx}}| < 3$ cm and $3 < |z_{\text{vtx}}| < 15$ cm, yielding uncertainties up to 6 and 5% in the centrality range 0–10%. Third, centrality calibration uncertainties, assessed by varying event selection criteria [18], contribute up to 6 and 3% in peripheral events. Finally, discrepancies between original track distributions generated by the HYDJET model [29] and those obtained after full detector simulation, reconstruction, and efficiency corrections produce systematic uncertainties up to 9 and 5%. The centrality dependence of these uncertainties varies with the analysis method: in two-particle correlations, the largest uncertainties appear in central collisions (9% for $v_4\{2, |\Delta\eta| > 2\}$), while in multiparticle cumulants, the maximum relative uncertainty is about 6% in mid-central to peripheral collisions. Overall, the various v_n coefficients show consistent systematic trends, with partial cancellation in the cumulant results due to correlations between numerator and denominator terms defined in Eqs. (12) to (15).

6. Description of the models

The IP-GLASMA initial-condition (IC) model is an event generator incorporating event-by-event geometric and subnucleonic quantum fluctuations through dependencies on the impact parameter and the longitudinal momentum fraction x , where x denotes the fraction of a nucleon's momentum carried by a quark or gluon in a high energy scattering process [30]. This model captures the fluctuating color charge configurations in ultrarelativistic nuclear collisions. The model has been shown to accurately reproduce experimental features of odd flow harmonics, particularly v_3 , which are known to be dominated by initial-state fluctuations [30].

The full IP-GLASMA + MUSIC + URQMD framework [31] builds upon the fluctuating initial states from IP-GLASMA-IC by incorporating hydrodynamic evolution using MUSIC [32], a second-order relativistic viscous

Fig. 1. The upper row shows $v_n\{2, |\Delta\eta| > 2\}$ for elliptic ($n = 2$, left), triangular ($n = 3$, middle), and quadrangular ($n = 4$, right) flow, as a function of centrality in XeXe and PbPb collisions, calculated using the 2-particle correlation method. The vertical bars (mostly smaller than the marker size) and the open boxes represent the statistical and systematic uncertainties, respectively. The shaded bands represent five different hydrodynamic predictions from the IP-GLASMA + MUSIC + URQMD model using four Xe parameter sets, and one Pb parameter set; the band widths indicate the statistical uncertainties of the model calculations. Some model predictions in the upper row are partially obscured due to overlap with others. The middle row compares various theoretical predictions to the data for the XeXe/PbPb ratios. The red and black solid lines show predictions using ratios of the initial-state eccentricities ϵ_n from the TRENTO-IC model with deformed (Xe (a)) and spherical (Xe (b)) parameters, respectively, both taken as ratios with respect to the Pb nucleus. The lower row shows the ratios of the hydrodynamic predictions to data.

Table 1

Woods–Saxon parameters used to model the nuclear density distributions for the ^{129}Xe nucleus in four different deformation configurations and for the ^{208}Pb nucleus. The parameters R_0 , a_0 , β_2 , and β_4 are defined in Eq. (3).

Nucleus	R_0 (fm)	a_0 (fm)	β_2	β_4
Xe (a)	5.601	0.492	0.207	-0.003
Xe (b)	5.420	0.570	0.000	-0.003
Xe (c)	5.420	0.570	0.162	-0.003
Xe (d)	5.420	0.570	0.207	-0.003
Pb	6.647	0.537	0.006	0.000

hydrodynamic program. The MUSIC simulation employs a fixed specific shear viscosity to entropy density ratio $\eta/s = 0.12$ and a temperature-dependent bulk viscosity $\zeta/s(T)$ for the QGP phase until hadronization. Afterward, resonance decays and hadronic rescattering are simulated with URQMD v3.4 [33,34] until kinetic freeze-out.

For this analysis, four sets of Woods–Saxon deformation parameters for Xe and one set for Pb are used. These deformation parameters originate from both theoretical calculations and empirical studies, and were provided by the authors of Ref. [30]. They are intended to span a representative range of plausible nuclear deformations for the Xe nuclei and are summarized in Table 1.

The TRENTO-IC model [35] is an initial-state model that does not assume any specific mechanism for pre-equilibrium dynamics, or thermalization. It deposits entropy in proportion to the generalized (typically geometric) mean of the nuclear overlap density between the colliding nuclei. This model simulates only the initial-state eccentricities, ϵ_n , and does not consider any final-state effects like hydrodynamic evolution or hadronic scattering. Eccentricities for XeXe collisions are found using only two sets of deformation parameters, Xe (a) for deformed and Xe (b) for spherical configurations.

7. Results

7.1. Sensitivity to nuclear deformation of the Xe nucleus

Fig. 1 presents the 2-particle correlation results for $v_n\{2, |\Delta\eta| > 2\}$ with $n = 2, 3, 4$ as a function of centrality for XeXe and PbPb collisions. The upper, middle, and lower rows show the v_n values, comparisons of model predictions to the data, and the ratios of the hydrodynamic model predictions to the data, respectively.

All three flow harmonics exhibit larger values in XeXe events than in PbPb data for lower centrality percentages, which correspond to more central collisions, but smaller values in peripheral collisions. This enhancement of v_2 in central XeXe collisions is likely driven by the quadrupole deformation of the Xe nucleus, while the larger v_3 compared to PbPb indicates stronger initial-state density fluctuations in XeXe [36]. In central collisions, enhanced values of v_4 in XeXe relative to PbPb col-

Fig. 2. The upper panels show $v_n\{4\}/v_n\{2, |\Delta\eta| > 2\}$ for elliptic ($n = 2$, left) and triangular ($n = 3$, right) flow, calculated from multiparticle cumulants, as a function of centrality in XeXe and PbPb collisions. The vertical bars (mostly smaller than the marker size) on the dots and the open boxes represent the statistical and systematic uncertainties in the data, respectively. The red and blue solid lines show the predictions from TRENTo-IC in terms of the initial-state eccentricities ϵ_n for deformed Xe (a) and Pb nuclei. The shaded bands show the hydrodynamic predictions from the IP-GLASMA + MUSIC + URQMD model for Xe (a) and Xe (d); the band widths indicate the statistical uncertainties of the model calculations. The lower panels display the ratio of the XeXe to the PbPb results. The cyan line in the lower right panel shows the theoretical prediction for $v_3\{4\}/v_3\{2, |\Delta\eta| > 2\}$ based on $A^{-1/4}$ scaling.

lisions can be interpreted as arising from larger event-by-event fluctuations. In contrast, in mid-central and peripheral collisions, v_4 is dominated by nonlinear coupling to v_2 [36,37]. Since v_2 is smaller in XeXe than in PbPb in this centrality range, the resulting nonlinear contribution to v_4 is reduced in XeXe, leading to XeXe/PbPb v_4 ratios below unity [36].

The middle row of Fig. 1 compares the XeXe/PbPb ratios to IP-GLASMA + MUSIC + URQMD and TRENTo-IC model predictions. The IP-GLASMA + MUSIC + URQMD hydrodynamic predictions are given for four Xe nuclear shape parameter sets [30], with statistical uncertainties shown as shaded bands. The TRENTo-IC model predicts the initial-state eccentricities ϵ_n and their ratios. The comparison to v_n ratios assumes an approximately linear hydrodynamic response, $v_n \propto \epsilon_n$, such that the flow ratios qualitatively reflect the corresponding eccentricity ratios. The predictions are displayed in Fig. 1 for v_2 using the Xe (a) and (b) sets, but only with the Xe (a) set for v_3 and v_4 due to their insensitivity to elliptical deformation. For a clearer comparison, the lower row in Fig. 1 displays the ratios of the hydrodynamic model predictions to data. Ratios are not shown for the TRENTo-IC model, as it provides initial-state eccentricities, while the ratios presented here involve final-state flow observables.

For the hydrodynamic model with parameter set (a), the largest value of the quadrupole deformation β_2 gives the best agreement for v_2 with a reduced $\chi^2/NDF \approx 0.99$, compared to values from 4.6 to 8.5 for the other sets. Set (d), having the same β_2 as set (a) but a larger value for the nuclear skin depth a_0 , describes the data slightly better than sets (b) or (c) for the 0–10% most central events ($\chi^2/NDF \approx 4.6$, as opposed to values of about 8.5 and 5.0 for sets (b) and (c), respectively). For v_3 , set (a) also fits best ($\chi^2/NDF \approx 1.7$, compared to $\chi^2/NDF > 4$ for the others) for the 20–70% centrality region, but is comparable or even slightly worse in other centrality regions. In the case of v_4 , all 4

sets give comparable predictions for the 0–20% centrality region, but set (a) performs best in the 20–70% centrality region ($\chi^2/NDF \approx 6.8$ overall, compared to $\chi^2/NDF > 20$ for the others).

The TRENTo-IC model gives a poor description of v_2 for peripheral events (beyond about 35–40% centrality) and fails to match v_3 and v_4 overall (except for extremely central collisions). These discrepancies are likely due to viscous damping effects, which are stronger in the smaller XeXe system [36]. However, for v_2 in the 0–20% centrality region, which is more sensitive to deformation, the predictions using the deformed Xe (a) parameters show better agreement with the data. In fact, this agreement is comparable to that for the hydrodynamic model using the same Xe parameter set.

Differences between models and data may arise from multiple factors. Integrated flow harmonics can be over- or underestimated due to differences in the p_T ranges, affecting extraction of QGP transport coefficients [η/s , $\zeta/s(T)$] [38]. The IP-GLASMA + MUSIC + URQMD simulations use $\eta/s = 0.12$, but theoretical uncertainties remain. The models also assume values of zero for both the octupole deformation (β_3) and triaxiality (γ) parameters, the latter describing deviations from axial symmetry. However, recent studies suggest that Xe nuclei exhibit large deformation fluctuations due to a second-order phase transition along the Xe isotope chain [39], which these models do not account for. Uncertainties in freeze-out criteria further impact predicted flow observables, contributing to discrepancies and uncertainties in extracting the Xe deformation parameters. In addition, in peripheral collisions, contributions from non-thermalized or pp-like (core–corona) events may influence the measured correlations, effects which are not fully captured by the hydrodynamic models [40]. While such contributions may partially cancel in the XeXe/PbPb ratios, some residual effects may remain due to differences in system size and geometry [41].

Fig. 3. The upper panels show the normalized symmetric cumulants $NSC(2,3)$ (left) and $NSC(2,4)$ (right) as functions of centrality in XeXe and PbPb collisions, calculated from multiparticle cumulants. The vertical bars and the open boxes represent the statistical and systematic uncertainties, respectively. The red and blue solid lines show the predictions from TRENTo-IC in terms of initial-state eccentricities ϵ_n for deformed Xe (Xe (a)) and Pb nuclei. The orange and green solid lines show the predictions from the IP-GLASMA-IC model with the same Xe and Pb nucleus parameters. The shaded bands show the hydrodynamic predictions from the IP-GLASMA + MUSIC + URQMD model; the band widths indicate the statistical uncertainties of the model calculations. The lower panels display the corresponding ratios of $NSC(m,n)$ for XeXe/PbPb. The red solid lines show the initial-state predictions from TRENTo-IC, while the green solid lines show those from IP-GLASMA-IC. The blue shaded band is the hydrodynamic prediction from IP-GLASMA + MUSIC + URQMD. In the 5–10% centrality range, the TRENTo-IC $NSC(2,4)$ ratio is negative because the PbPb prediction lies just below zero.

The observable $v_n\{4\}/v_n\{2, |\Delta\eta| > 2\}$ provides direct information about event-by-event fluctuations of v_n [36]. If v_n fluctuates between events, this ratio is smaller than 1. The values of $v_2\{4\}/v_2\{2, |\Delta\eta| > 2\}$ exhibit a significant centrality dependence, as shown in the upper left panel of Fig. 2, with the largest deviation from unity occurring in more central events. The systematically larger deviations from unity in XeXe compared to PbPb events indicate larger elliptic flow fluctuations in XeXe collisions. These trends are also observed in both the initial-state TRENTo-IC and hydrodynamic IP-GLASMA + MUSIC + URQMD predictions. In Ref. [38], this observable was shown to be sensitive to a_0 , which characterizes the degree of nuclear diffuseness. A smaller a_0 corresponds to a sharper nuclear surface, which reduces event-by-event fluctuations of the initial elliptic geometry, particularly in semi-central collisions. As a result, the $v_2\{4\}/v_2\{2, |\Delta\eta| > 2\}$ ratio is less suppressed [38].

To further investigate this sensitivity, the double ratio of $v_2\{4\}/v_2\{2, |\Delta\eta| > 2\}$ for XeXe to PbPb values is shown in the lower left panel of Fig. 2. The theoretical predictions using parameter set Xe (a) with $a_0 = 0.492$ more closely match the data than set (d) with $a_0 = 0.570$, reinforcing the conclusion based on $v_2\{2, |\Delta\eta| > 2\}$ alone.

In the following discussion, the IP-GLASMA + MUSIC + URQMD predictions for XeXe collisions will use only parameter set Xe (a), which provides the closest match to data. For higher-order cumulants, all parameter sets remain compatible within the uncertainties.

7.2. Nonlinear hydrodynamic response through higher-order moments of flow harmonics

The upper left panel in Fig. 2 also shows that the ratios $\epsilon_2\{4\}/\epsilon_2\{2\}$ from TRENTo-IC (solid lines) exceed the corresponding v_2 ratios in

more peripheral collisions, indicating a nonlinear hydrodynamic response that increases towards peripheral collisions [7]. This effect is more pronounced in XeXe collisions (starting from around 30% centrality, as opposed to 50% centrality in PbPb collisions), suggesting stronger nonlinearity in the smaller XeXe system. The same nonlinear response is also observed in the upper right panel of Fig. 2, where the predictions from TRENTo-IC for $\epsilon_3\{4\}/\epsilon_3\{2\}$ (solid lines) exceed the corresponding v_3 ratios. In contrast to what was seen for v_2 , the values of $v_3\{4\}/v_3\{2, |\Delta\eta| > 2\}$ for both the predictions and the data are closer to unity for XeXe than for PbPb collisions. Finite-size corrections to the central limit theorem, which induce non-Gaussian fluctuations in the initial triangularity ϵ_3 , were predicted to result in an $A^{-1/4}$ scaling of $v_3\{4\}/v_3\{2, |\Delta\eta| > 2\}$ (where A is the atomic mass number) [36]. The non-Gaussian fluctuations scale with the number of participant nucleons, which roughly scales with A , leading to the observed scaling behavior. The lower right panel in Fig. 2 shows the XeXe/PbPb ratio, with the cyan line representing $(129/208)^{-1/4} \approx 1.13$, which agrees with the data within uncertainties.

The actual values of $v_2\{4\}$ and $v_3\{4\}$, without normalization by $v_n\{2, |\Delta\eta| > 2\}$, are given in Appendix A.

7.2.1. Normalized symmetric cumulants involving two or three flow harmonics

Fig. 3 presents the normalized four-particle symmetric cumulants involving two harmonics, $NSC(2,3)$ (left) and $NSC(2,4)$ (right), as functions of centrality in XeXe and PbPb collisions. In order to suppress nonflow effects, these are calculated using two particles from each of two separated η regions: $-2.4 < \eta < -1$ and $1 < \eta < 2.4$. The $NSC(2,3)$ values probe the interplay between elliptic and triangular fluctuations

Fig. 4. A selection of six-particle three-harmonic SC and NSC cumulants as functions of centrality in XeXe (left) and PbPb (right) collisions, calculated from multiparticle cumulants. The vertical bars represent the statistical uncertainties, with the systematic uncertainties being negligible. The shaded bands show hydrodynamic predictions from the IP-GLASMA + MUSIC + URQMD model for the Xe (a) deformed nuclear shape parameters and for the spherical Pb nucleus; the band widths indicate the statistical uncertainties of the model calculations. The solid lines represent initial-state model predictions from TRENTo-IC.

Fig. 5. Six-particle normalized mixed harmonic cumulants (nMHC) as functions of centrality in XeXe and PbPb collisions, calculated from multiparticle cumulants. Upper panels: $nMHC(v_2^4, v_3^2)$ (left) and $nMHC(v_2^4, v_4^2)$ (right). Lower panels: $nMHC(v_2^2, v_3^4)$ (left) and $nMHC(v_2^2, v_4^4)$ (right). The vertical bars represent the statistical uncertainties and the systematic uncertainties are negligible. The shaded bands show hydrodynamic predictions from the IP-GLASMA + MUSIC + URQMD model for deformed Xe (Xe (a)) and Pb nuclei; the band widths indicate the statistical uncertainties of the model calculations. The solid lines represent initial-state model predictions.

influenced by eccentricities and deformation, while NSC(2, 4) is sensitive to nonlinear mode couplings and higher-multipole nuclear deformations (e.g., β_4), providing complementary constraints on the initial geometry. The results show that v_2^2 and v_3^2 are anticorrelated across all centralities, reflecting the anticorrelation between initial eccentricities ϵ_2 and ϵ_3 , whereas v_2^2 and v_4^2 are positively correlated due to nonlinear mode coupling, where v_4 receives contributions proportional to ϵ_2^2 [22]. The lower panels display the XeXe/PbPb ratios of NSC(2, 3) and NSC(2, 4), highlighting the differences between the initial states of the two systems.

The IP-GLASMA + MUSIC + URQMD hydrodynamic model captures the trends of both NSC(2, 3) and NSC(2, 4), albeit with a slight underestimation of the deviation from zero in some cases. Initial-state TRENTO-IC and IP-GLASMA-IC models reproduce NSC(2, 3) except in peripheral collisions, where the linear relations $v_2 \propto \epsilon_2$ and $v_3 \propto \epsilon_3$ slightly break down [7]. For NSC(2, 4), initial-state models increasingly underestimate the data from central to peripheral collisions, highlighting that these models lack the dynamical nonlinear mode-coupling generated during hydrodynamic expansion, through which v_4 receives a significant contribution proportional to ϵ_2^2 .

For the XeXe/PbPb ratios shown in the lower row of Fig. 3, IP-GLASMA + MUSIC + URQMD, IP-GLASMA-IC, and TRENTO-IC all give roughly comparable agreement with the NSC(2, 3) data, with different models being closer to the data in different regions of centrality. Surprisingly, the ratios are well described even in the centrality regions where the two IC models fail to reproduce the individual XeXe and PbPb results. For the NSC(2, 4) ratios, the IP-GLASMA + MUSIC + URQMD model gives a reasonable description of the data, while the two IC models (especially the TRENTO-IC model) do notably worse. As was the case for the NSC(2, 3) ratios, the NSC(2, 4) ratios from the IC models are much closer to the data than the individual XeXe and PbPb values. These comparisons highlight the role of NSC(2, 3) and NSC(2, 4) in constraining the

initial-state geometry and its fluctuations, helping discriminate between different models of the initial entropy deposition and different sets of nuclear deformation parameters. This is because NSC(2, 3) is highly sensitive to correlations between the initial-state eccentricities ϵ_2 and ϵ_3 , while NSC(2, 4), through its dependence on v_4 , probes higher-order geometric structure and nonlinear mode-mixing effects.

Fig. 4 presents six-particle symmetric cumulants $SC(k, l, m)$ and their normalized counterparts $NSC(k, l, m)$ versus centrality for XeXe collisions (left) measured for the first time, and PbPb collisions (right). The upper rows display $SC(2, 3, 4)$, $SC(2, 3, 5)$, $SC(3, 4, 5)$, and $SC(2, 4, 6)$, while the lower rows show $NSC(2, 3, 4)$ and $NSC(2, 3, 5)$ in both systems. These measurements reveal genuine correlations among three different flow harmonics. In particular, the nonzero NSC(2, 3, 4) values indicate fluctuations in the elliptical shape of the nuclear overlap region, beyond mere magnitude fluctuations of elliptic deformation [27]. The NSC(2, 3, 4) values in XeXe and PbPb are similar in the most central collisions, while in the mid-central range (15–45%) the XeXe values are systematically larger in magnitude, suggesting moderately stronger shape fluctuations in the initial geometry. The $SC(3, 4, 5)$ values are consistent with zero in both systems, as seen in Refs. [27, 42], while the other $SC(k, l, m)$ cumulants have finite values. Notably, $SC(2, 3, 5)$ and $NSC(2, 3, 5)$ show different trends in XeXe collisions, possibly indicating more nonlinear contribution for v_5 from v_2 and v_3 in the smaller system, with an even larger difference for the NSC data [42].

Hydrodynamic IP-GLASMA + MUSIC + URQMD calculations provide an overall good description of the individual $SC(k, l, m)$ observables, but tend to underestimate the values of $NSC(k, l, m)$ in certain centrality intervals. In contrast, the initial-state TRENTO-IC predictions systematically underestimate $NSC(k, l, m)$, with the discrepancy becoming more pronounced toward peripheral collisions. As for the four-particle sym-

Fig. 6. Eight-particle normalized mixed harmonic cumulants (nMHC) as functions of centrality in XeXe and PbPb collisions, calculated from multiparticle cumulants. Left panels: $nMHC(v_2^6, v_3^2)$ (upper), $nMHC(v_2^4, v_3^4)$ (middle), and $nMHC(v_2^2, v_3^6)$ (lower). Right panels: $nMHC(v_2^6, v_2^4)$ (upper), $nMHC(v_2^4, v_2^4)$ (middle), and $nMHC(v_2^2, v_2^4)$ (lower). The vertical bars represent statistical uncertainties and the systematic uncertainties are negligible. The shaded bands show hydrodynamic predictions from the IP-GLASMA + MUSIC + URQMD model for deformed Xe (Xe (a)) and Pb nuclei; the band widths indicate the statistical uncertainties of the model calculations. The solid lines represent initial-state model predictions.

metric cumulants, this behaviour observed in TRENTO-IC predictions is again attributed to the dynamical development of multiharmonic correlations during the hydrodynamic evolution of the medium, in particular due to nonlinear hydrodynamic contributions to v_4 and v_5 arising from v_2 and v_3 [22,42].

7.2.2. Correlations between higher-order moments of two flow harmonics

Figs. 5 and 6 present the first comparisons of $\text{nMHC}(v_2^k, v_3^l)$ and $\text{nMHC}(v_2^k, v_4^l)$ from XeXe and PbPb collisions for $k, l = 2, 4, 6$. The specific combinations are indicated in each panel. A key observation is that the magnitudes of $\text{nMHC}(v_2^k, v_4^l)$ are larger than the corresponding values of $\text{nMHC}(v_2^k, v_3^l)$ for the same k and l in both collision systems (note the differences in vertical scale between the left and right panels in both figures). This indicates a stronger correlation between higher order moments of v_2 and v_4 , consistent with the trend observed for NSC(2,4) versus NSC(2,3). This can be attributed to the fact that both v_2 and v_4 are strongly influenced by the initial-state geometry.

A distinct pattern is observed in the magnitudes of correlations involving v_3 :

$$|\text{nMHC}(v_2^6, v_3^2)| > |\text{nMHC}(v_2^4, v_3^2)| > |\text{nMHC}(v_2^4, v_3^4)| \\ > |\text{nMHC}(v_2^2, v_3^4)| > |\text{nMHC}(v_2^2, v_3^6)|, \quad (16)$$

similar to the findings in Ref. [22].

For v_4 , the sequence differs slightly, with the second and third terms swapped:

$$|\text{nMHC}(v_2^6, v_4^2)| > |\text{nMHC}(v_2^4, v_4^4)| > |\text{nMHC}(v_2^4, v_4^2)| \\ > |\text{nMHC}(v_2^2, v_4^4)| > |\text{nMHC}(v_2^2, v_4^6)|. \quad (17)$$

Since v_2 and v_4 are strongly correlated, the inequality $|\text{nMHC}(v_2^4, v_4^4)| > |\text{nMHC}(v_2^2, v_4^2)|$ suggests that mode couplings involving equal orders of v_2 and v_4 exhibit stronger correlations.

System-size effects show a consistent trend across different $\text{nMHC}(v_2^k, v_3^l)$ and $\text{nMHC}(v_2^k, v_4^l)$ combinations. Given that initial-state fluctuations are expected to be stronger in the smaller XeXe system, correlations involving higher-order moments of v_3 and v_4 ($v_3^4, v_3^6, v_4^4, v_4^6$) correlated with lower-order moments of v_2 (v_2^2) show enhanced values in XeXe data, reflecting their greater sensitivity to fluctuations.

For correlations between v_2 and v_3 , the four-, six-, and eight-particle cumulants are found to have negative, positive, and negative correlations, respectively, in both XeXe and PbPb collisions, in qualitative agreement with initial-state TRENTO-IC predictions [43]. For example, comparing the upper left panels of Figs. 3, 5, and 6: NSC(2,3) (4-particle), $\text{nMHC}(v_2^4, v_3^2)$ (6-particle), and $\text{nMHC}(v_2^6, v_3^2)$ (8-particle) follow this negative, positive, negative pattern.

However, this pattern does not hold for correlations between v_2 and v_4 : correlations involving higher-order moments of v_4 ($l = 4, 6$) swap signs for the same order n -particle cumulant. For instance, $\text{nMHC}(v_2^4, v_4^2)$ and $\text{nMHC}(v_2^2, v_4^4)$ have negative and positive correlations, respectively, despite both being 6-particle cumulants.

The right hand panels in Figs. 5 and 6 compare the hydrodynamic and initial-state model predictions for correlations of various orders of v_2 and v_4 , similar to previous studies using v_2 and v_3 [22]. While the hydrodynamic models qualitatively reproduce all of the observed trends, initial-state models exhibit striking disagreements in the correlations of $\text{nMHC}(v_2^2, v_4^4)$, $\text{nMHC}(v_2^4, v_4^4)$, and $\text{nMHC}(v_2^2, v_4^6)$, predicting correlations opposite in sign to what is observed. This discrepancy likely arises because these observables depend on fourth- and sixth-order moments of v_4 , which experience nonlinear hydrodynamic responses to ε_2 that grow towards peripheral collisions. This reinforces the conclusion that correlations between v_2 and v_4 predominantly develop dynamically during system evolution, rather than being fully determined by initial-state correlations. These correlations primarily arise from nonlinear hydrodynamic response and are influenced by transport properties such as shear and bulk viscosities [22].

Table 2 summarizes the signs of the correlations observed for different moments of v_2 and v_3/v_4 as functions of centrality.

Table 2

Signs of correlations between different moments of v_2 and v_3/v_4 as functions of centrality.

n -particle cumulant	Quantity	Correlation sign	Quantity	Correlation sign
4	NSC(2,3)	-	NSC(2,4)	+
6	$\text{nMHC}(v_2^4, v_3^2)$	+	$\text{nMHC}(v_2^4, v_3^2)$	-
6	$\text{nMHC}(v_2^2, v_3^4)$	+	$\text{nMHC}(v_2^2, v_4^4)$	+
8	$\text{nMHC}(v_2^6, v_3^2)$	-	$\text{nMHC}(v_2^6, v_3^2)$	+
8	$\text{nMHC}(v_2^4, v_3^4)$	-	$\text{nMHC}(v_2^4, v_4^4)$	-
8	$\text{nMHC}(v_2^2, v_3^6)$	-	$\text{nMHC}(v_2^2, v_4^6)$	-(within uncertainties)

8. Summary

For the first time, individual flow harmonics, two- and three-harmonic correlations, and higher-order mixed harmonic cumulants are measured and compared in detail for xenon-xenon (XeXe) and lead-lead (PbPb) collisions at $\sqrt{s_{NN}} = 5.44$ and 5.36 TeV, respectively. Theoretical predictions of the IP-GLASMA + MUSIC + URQMD hydrodynamic model, and the TRENTO-IC and IP-GLASMA-IC initial-state models, calculated with various sets of deformation parameters for the ^{129}Xe nucleus, are compared to the data. The final-state model calculation from IP-GLASMA + MUSIC + URQMD with nuclear deformation parameters $a_0 = 0.492$ and $\beta_2 = 0.207$ for ^{129}Xe provides the best agreement among tested parameter sets. Here, a_0 is the nuclear skin depth, and β_2 is the quadrupole deformation parameter. This comparison indicates that including a prolate deformation in the parameterization of the ^{129}Xe nuclear shape (in contrast to the doubly magic, nearly spherical ^{208}Pb nucleus) is necessary to reproduce the measured flow observables within the IP-GLASMA + MUSIC + URQMD framework.

On the other hand, the difference in initial-state predictions from the TRENTO-IC and IP-GLASMA-IC models not only point to the sensitivity of these observables to the pre-equilibrium dynamics needed to model the experimental data, but also to the increasing nonlinearity of the higher-order moments of the flow harmonics in peripheral collisions. While differences between the two initial-state models are visible, a definitive conclusion about their relative performance cannot be drawn, as such a comparison without the inclusion of hydrodynamic evolution and freeze-out stages remains incomplete.

The comparison of higher-order moments in XeXe and PbPb collisions provides insight into the impact of system size and shape on these observables. Measurements involving higher-order moments of fluctuation-driven flow harmonics, such as v_3 and v_4 , are, as expected, larger in the smaller XeXe system.

Subtle differences exist between data and model calculations with the current sets of parameters. These differences highlight the importance of fine-tuning the model parameters, including not only the nuclear deformation parameters but also those related to hydrodynamic calculations, such as transport coefficients and freeze-out criteria. Such analyses can significantly improve the overall understanding of initial conditions in heavy ion collisions and transport properties of the quark-gluon plasma created at the LHC. Furthermore, this work provides a data-driven, multi-faceted probe of flow fluctuations, offering direct sensitivity to correlations arising from nonlinear hydrodynamic response.

Data availability

Release and preservation of data used by the CMS Collaboration as the basis for publications is guided by the [CMS data preservation, re-use and open access policy](#).

Declaration of competing interest

- ¹⁷⁹ University of California, Santa Barbara - Department of Physics, Santa Barbara, California, USA
- ¹⁸⁰ California Institute of Technology, Pasadena, California, USA
- ¹⁸¹ Carnegie Mellon University, Pittsburgh, Pennsylvania, USA
- ¹⁸² University of Colorado Boulder, Boulder, Colorado, USA
- ¹⁸³ Cornell University, Ithaca, New York, USA
- ¹⁸⁴ Fermi National Accelerator Laboratory, Batavia, Illinois, USA
- ¹⁸⁵ University of Florida, Gainesville, Florida, USA
- ¹⁸⁶ Florida State University, Tallahassee, Florida, USA
- ¹⁸⁷ Florida Institute of Technology, Melbourne, Florida, USA
- ¹⁸⁸ University of Illinois Chicago, Chicago, Illinois, USA
- ¹⁸⁹ The University of Iowa, Iowa City, Iowa, USA
- ¹⁹⁰ Johns Hopkins University, Baltimore, Maryland, USA
- ¹⁹¹ The University of Kansas, Lawrence, Kansas, USA
- ¹⁹² Kansas State University, Manhattan, Kansas, USA
- ¹⁹³ University of Maryland, College Park, Maryland, USA
- ¹⁹⁴ Massachusetts Institute of Technology, Cambridge, Massachusetts, USA
- ¹⁹⁵ University of Minnesota, Minneapolis, Minnesota, USA
- ¹⁹⁶ University of Nebraska-Lincoln, Lincoln, Nebraska, USA
- ¹⁹⁷ State University of New York at Buffalo, Buffalo, New York, USA
- ¹⁹⁸ Northeastern University, Boston, Massachusetts, USA
- ¹⁹⁹ Northwestern University, Evanston, Illinois, USA
- ²⁰⁰ University of Notre Dame, Notre Dame, Indiana, USA
- ²⁰¹ The Ohio State University, Columbus, Ohio, USA
- ²⁰² Princeton University, Princeton, New Jersey, USA
- ²⁰³ University of Puerto Rico, Mayaguez, Puerto Rico, USA
- ²⁰⁴ Purdue University, West Lafayette, Indiana, USA
- ²⁰⁵ Purdue University Northwest, Hammond, Indiana, USA
- ²⁰⁶ Rice University, Houston, Texas, USA
- ²⁰⁷ University of Rochester, Rochester, New York, USA
- ²⁰⁸ Rutgers, The State University of New Jersey, Piscataway, New Jersey, USA
- ²⁰⁹ University of Tennessee, Knoxville, Tennessee, USA
- ²¹⁰ Texas A&M University, College Station, Texas, USA
- ²¹¹ Texas Tech University, Lubbock, Texas, USA
- ²¹² Vanderbilt University, Nashville, Tennessee, USA
- ²¹³ University of Virginia, Charlottesville, Virginia, USA
- ²¹⁴ Wayne State University, Detroit, Michigan, USA
- ²¹⁵ University of Wisconsin - Madison, Madison, Wisconsin, USA
- ²¹⁶ Authors affiliated with an international laboratory covered by a co-operation agreement with CERN
- ²¹⁷ Authors affiliated with an institute formerly covered by a cooperation agreement with CERN
- ²¹⁸ Deceased
- ²¹⁹ Also at Yerevan State University, Yerevan, Armenia
- ²²⁰ Also at TU Wien, Vienna, Austria
- ²²¹ Also at Ghent University, Ghent, Belgium
- ²²² Also at Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil
- ²²³ Also at FACAMP - Faculdades de Campinas, Sao Paulo, Brazil
- ²²⁴ Also at Universidade Estadual de Campinas, Campinas, Brazil
- ²²⁵ Also at Federal University of Rio Grande do Sul, Porto Alegre, Brazil
- ²²⁶ Also at The University of the State of Amazonas, Manaus, Brazil
- ²²⁷ Also at University of Chinese Academy of Sciences, Beijing, China
- ²²⁸ Also at China Center of Advanced Science and Technology, Beijing, China
- ²²⁹ Now at Henan Normal University, Xinxiang, China
- ²³⁰ Also at University of Shanghai for Science and Technology, Shanghai, China
- ²³¹ Now at The University of Iowa, Iowa City, Iowa, USA
- ²³² Also at Center for High Energy Physics, Peking University, Beijing, China
- ²³³ Also at Cairo University, Cairo, Egypt
- ²³⁴ Also at Suez University, Suez, Egypt
- ²³⁵ Now at British University in Egypt, Cairo, Egypt
- ²³⁶ Also at Purdue University, West Lafayette, Indiana, USA
- ²³⁷ Also at Université de Haute Alsace, Mulhouse, France
- ²³⁸ Also at Istinye University, Istanbul, Turkey
- ²³⁹ Also at Tbilisi State University, Tbilisi, Georgia
- ²⁴⁰ Also at an institute formerly covered by a cooperation agreement with CERN
- ²⁴¹ Also at University of Hamburg, Hamburg, Germany
- ²⁴² Also at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany
- ²⁴³ Also at Bergische University Wuppertal (BUW), Wuppertal, Germany
- ²⁴⁴ Also at Brandenburg University of Technology, Cottbus, Germany
- ²⁴⁵ Also at Forschungszentrum Jülich, Jülich, Germany
- ²⁴⁶ Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland
- ²⁴⁷ Also at HUN-REN ATOMKI - Institute of Nuclear Research, Debrecen, Hungary
- ²⁴⁸ Now at Universitatea Babeş-Bolyai - Facultatea de Fizica, Cluj-Napoca, Romania
- ²⁴⁹ Also at MTA-ELTE Lendület CMS Particle and Nuclear Physics Group, Eötvös Loránd University, Budapest, Hungary
- ²⁵⁰ Also at HUN-REN Wigner Research Centre for Physics, Budapest, Hungary
- ²⁵¹ Also at Physics Department, Faculty of Science, Assiut University, Assiut, Egypt
- ²⁵² Also at The University of Kansas, Lawrence, Kansas, USA
- ²⁵³ Also at Punjab Agricultural University, Ludhiana, India
- ²⁵⁴ Also at University of Hyderabad, Hyderabad, India
- ²⁵⁵ Also at Indian Institute of Science (IISc), Bangalore, India
- ²⁵⁶ Also at University of Visva-Bharati, Santiniketan, India
- ²⁵⁷ Also at IIT Bhubaneswar, Bhubaneswar, India
- ²⁵⁸ Also at Institute of Physics, Bhubaneswar, India

²⁵⁹ Also at Deutsches Elektronen-Synchrotron, Hamburg, Germany
²⁶⁰ Also at Isfahan University of Technology, Isfahan, Iran
²⁶¹ Also at Sharif University of Technology, Tehran, Iran
²⁶² Also at Department of Physics, University of Science and Technology of Mazandaran, Behshahr, Iran
²⁶³ Also at Department of Physics, Faculty of Science, Arak University, ARAK, Iran
²⁶⁴ Also at Helwan University, Cairo, Egypt
²⁶⁵ Also at Italian National Agency for New Technologies, Energy and Sustainable Economic Development, Bologna, Italy
²⁶⁶ Also at Centro Siciliano di Fisica Nucleare e di Struttura Della Materia, Catania, Italy
²⁶⁷ Also at Università degli Studi Guglielmo Marconi, Roma, Italy
²⁶⁸ Also at Scuola Superiore Meridionale, Università di Napoli 'Federico II', Napoli, Italy
²⁶⁹ Also at Fermi National Accelerator Laboratory, Batavia, Illinois, USA
²⁷⁰ Also at Lulea University of Technology, Lulea, Sweden
²⁷¹ Also at Consiglio Nazionale delle Ricerche - Istituto Officina dei Materiali, Perugia, Italy
²⁷² Also at UPES - University of Petroleum and Energy Studies, Dehradun, India
²⁷³ Also at Institut de Physique des 2 Infinis de Lyon (IP2I), Villeurbanne, France
²⁷⁴ Also at Department of Applied Physics, Faculty of Science and Technology, Universiti Kebangsaan Malaysia, Bangi, Malaysia
²⁷⁵ Also at Trincomalee Campus, Eastern University, Sri Lanka, Nilaveli, Sri Lanka
²⁷⁶ Also at Saegis Campus, Nugegoda, Sri Lanka
²⁷⁷ Also at National and Kapodistrian University of Athens, Athens, Greece
²⁷⁸ Also at Ecole Polytechnique Fédérale Lausanne, Lausanne, Switzerland
²⁷⁹ Also at Universität Zürich, Zurich, Switzerland
²⁸⁰ Also at Stefan Meyer Institute for Subatomic Physics, Vienna, Austria
²⁸¹ Also at Near East University, Research Center of Experimental Health Science, Mersin, Turkey
²⁸² Also at Konya Technical University, Konya, Turkey
²⁸³ Also at Izmir Bakircay University, Izmir, Turkey
²⁸⁴ Also at Adiyaman University, Adiyaman, Turkey
²⁸⁵ Also at Bozok Universitetesi Rektörlüğü, Yozgat, Turkey
²⁸⁶ Also at Istanbul Sabahattin Zaim University, Istanbul, Turkey
²⁸⁷ Also at Marmara University, Istanbul, Turkey
²⁸⁸ Also at Milli Savunma University, Istanbul, Turkey
²⁸⁹ Also at Informatics and Information Security Research Center, Gebze/Kocaeli, Turkey
²⁹⁰ Also at Kafkas University, Kars, Turkey
²⁹¹ Now at Istanbul Okan University, Istanbul, Turkey
²⁹² Also at Hacettepe University, Ankara, Turkey
²⁹³ Also at Erzincan Binali Yildirim University, Erzincan, Turkey
²⁹⁴ Also at Istanbul University - Cerrahpasa, Faculty of Engineering, Istanbul, Turkey
²⁹⁵ Also at Yildiz Technical University, Istanbul, Turkey
²⁹⁶ Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom
²⁹⁷ Also at Monash University, Faculty of Science, Clayton, Australia
²⁹⁸ Also at Bethel University, St. Paul, Minnesota, USA
²⁹⁹ Also at Università di Torino, Torino, Italy
³⁰⁰ Also at Karamanoğlu Mehmetbey University, Karaman, Turkey
³⁰¹ Also at California Lutheran University, Thousand Oaks, California, USA
³⁰² Also at California Institute of Technology, Pasadena, California, USA
³⁰³ Also at United States Naval Academy, Annapolis, Maryland, USA
³⁰⁴ Also at Bingol University, Bingol, Turkey
³⁰⁵ Also at Georgian Technical University, Tbilisi, Georgia
³⁰⁶ Also at Sinop University, Sinop, Turkey
³⁰⁷ Also at Erciyes University, Kayseri, Turkey

³⁰⁸ Also at Horia Hulubei National Institute of Physics and Nuclear Engineering (IFIN-HH), Bucharest, Romania
³⁰⁹ Now at another institute formerly covered by a cooperation agreement with CERN
³¹⁰ Also at Hamad Bin Khalifa University (HBKU), Doha, Qatar
³¹¹ Also at another institute formerly covered by a cooperation agreement with CERN
³¹² Also at Yerevan Physics Institute, Yerevan, Armenia
³¹³ Also at Imperial College, London, United Kingdom
³¹⁴ Also at Institute of Nuclear Physics of the Uzbekistan Academy of Sciences, Tashkent, Uzbekistan
